ENGINE TIMING SENSOR

Together with the rpm and TDC signal, the engine timing signal allows the ECU to recognise the order of cylinders during phased injection.

This signal is generated by a Hall sensor fitted on the exhaust camshaft pulley.

NOTE *Angular sensor position cannot be adjusted in any way.*

Principle of operation

A semi-conducting layer with current flowing through it is placed in a normal magnetic field (force lines at right angles to current direction). A potential difference known as a HALL voltage is set up at its terminals. If current intensity remains constant, the voltage generated depends only on magnetic field intensity. Intensity only needs to alter at intervals to obtain a modulated electrical signal with frequency proportional to speed with which magnetic field changes.

To achieve this change, the sensor is crossed by a metal ring (internal part of pulley) with an opening. The moving metal part of the ring covers the sensor and blocks the magnetic field to produce a low output signal. The sensor generates a high signal when aligned with the opening, i.e. with magnetic field present.

The alternation of signals is therefore dependent on the succession of openings (see chapter on "signal management").
